AN HLLC SCHEME TO SOLVE THE $M_1$ MODEL OF RADIATIVE TRANSFER IN TWO SPACE DIMENSIONS

CHRISTOPHE BERTHON$^{1,1}$, PIERRE CHARRIER$^1$, AND BRUNO DUBROCA$^{1,5}$

Abstract. The $M_1$ radiative transfer model is considered in the present work in order to simulate the radiative fields and their interactions with the matter. The model is governed by an hyperbolic system of conservation laws supplemented by relaxation source terms. Several difficulties arise when approximating the solutions of the model; namely the positiveness of the energy, the flux limitation and the limit diffusion behavior have to be satisfied. An HLLC scheme is exhibited and it is shown to satisfy all the required properties. A particular attention is paid concerning the approximate extreme waves. These approximations are crucial to obtain an accurate scheme. The extension to the full 2D problem is proposed. It satisfies, once again, all the expected properties. Numerical experiments are proposed. They show that the considered scheme is actually less diffusive than the currently used numerical methods.

Key words. Radiative transfer, $M_1$ model, Asymptotic preserving, HLLC scheme, Positiveness and flux limitation.

AMS subject classifications. classification AMS

1. Introduction. In many applications involving radiative transfer, solving the full radiative transfer equation is too expensive. A great effort was devoted in recent years to derive cheaper relevant models. A new alternative was introduced by Dubroca and Feugeas [10]; namely the $M_1$ model. It has been used in a large literature (for instance see Turpault [25], Charrier et al [9] or Ripoll [20, 21]). The $M_1$ model is known to preserve several crucial properties of the radiative transfer equations such as the positiveness of energy, the flux limitation, the conservation of the total energy. In addition, it recovers the asymptotic diffusion regime in the limit of large opacities (see Mihalas and Mihalas [18] or Pourraning [19]). Another important property satisfied by this model concerns 2D simulations where the shadow cone is preserved in transparent regions.

One of the main difficulties to approximate solutions is to derive numerical schemes preserving all the above properties. In Dubroca and Feugeas [10], an HLL scheme (see Harten, Lax and van Leer [14] for details) is proposed which satisfies the positiveness of the energy and the flux limitation property. This first numerical approach is shown to fail concerning the asymptotic preserving property since it does not yield to relevant numerical approximation in the diffusion limit (for instance, see Audit et al [1]). Next, in the work of Buet and Cordier [6], the authors propose a two step method based on a relaxation scheme step (see Jin and Xin [16] but also Bouchut [3] or Berthon [3] for details of the relaxation scheme in several frameworks) and a well-balanced scheme step (see Bouchut [3], Gosse and Toscani [13] and references therein), and the obtained numerical method is shown to satisfy stability properties for a simplified 1D scattering model. However, in [4], the authors establish that the scheme proposed in [6] is still too much diffusive and they detail a new relaxation numerical approach with better accuracy. From the work [4, 6], the diffusion comes with the choice of the numerical extreme wavespeeds. In [6], these wavespeeds are

approximated when involving a unique constant. As announced in [4], in the present work, we propose relevant numerical approximations of each extreme wavespeed in each cell when involving a suitable approximate Riemann solver. The discrepancy with current works (see [6, 13]), stays in the structure of the approximate Riemann solver. Indeed, in the present work we consider, roughly speaking, non-symmetric approximate characteristic cone when usual approaches impose a symmetric wave cone. Such an independent consideration of the approximated wavespeed increases the accuracy of the method. Let us note from now on that the approximate characteristic cone defined by the extreme waves is of primary importance to satisfy the asymptotic preserving property. Now, if the approximate characteristic cone is too large, the numerical diffusion of the scheme increases and then the accuracy of the scheme is lost. By opposition, the scheme becomes unstable as soon as approximate characteristic cone is a too much narrow.

Arguing recent works, devoted to simplified one space dimension models, we develop an HLLC scheme for the $M_1$ model (see Batten et al [2], Bouchut [5], Toro et al [22, 23] to further details concerning the HLLC scheme in the framework of the standard gas dynamics). The structure of the approximate Riemann solver, used to define the HLLC scheme, is analysed and required stability results are established. To be more precise, we prove that the scheme satisfies the positiveness of the energy, the flux limitation property, the conservation of the total energy and the asymptotic preserving property. Next, a two space dimension extension of the scheme is proposed. To enforce the asymptotic diffusion behaviors of the 2D model, we propose to consider a relevant splitting technique of the relaxation source terms. The 2D final scheme is shown to satisfy all the required stability properties and it performs relevant numerical approximations when considering the asymptotic regimes. Moreover, thanks to the correct definition of the extreme wavespeeds, it preserves the stationary contact discontinuity which is crucial in some simulations.

The paper is organized as follows. In the next section, the $M_1$ model is described. The main properties satisfied by the solutions of the model are given. A special attention is paid on the asymptotic diffusion limit. In addition, the hyperbolic system is studied when giving the eigenvalues. The third section is devoted to describe an HLLC scheme to approximate the solution of the 1D model. A term by term operator splitting strategy is considered to propose a relevant method of approximation. All the properties satisfied by the exact solutions are proved to be verified by the approximate solutions. In the next section, we propose to extend the numerical scheme in the case of the 2D model. Once again, the obtained numerical scheme is shown to satisfy all the required properties. In the section five, numerical experiments are proposed. Specific 2D tests are performed to illustrate the diffuseless of the scheme. The last section is devoted to a short conclusion.

2. The $M_1$ model for radiative transfer. For many applications, solving the radiative transfer equation is too expensive and cheaper moment systems, such as the $M_1$ model, giving accurate enough prediction of interaction of radiation and matter are preferred. To derive such systems, we take the first two moments of the radiative transfer equation (see [10]) which leads to the following moment system:

$$
\partial_t E + \nabla \cdot F = c \sigma (aT^4 - E), \quad (2.1a)
$$

$$
\frac{1}{c} \partial_t F + c \nabla \cdot P = -\sigma F, \quad (2.1b)
$$

$$
\partial_t (\rho C_v T) = -c \sigma (aT^4 - E) \quad (2.1c)
$$
where E is the **radiative energy**, \( \mathbf{F} \) is the **the radiative flux vector** and \( \mathbf{P} \) is the **radiative pressure tensor**. The normalized flux is written as \( \mathbf{f} = \mathbf{F}/(cE) \) and \( f = || \mathbf{f} || \) and the radiative temperature \( T_R \) is defined from the radiative energy as \( E = aT_R^4 \).

The radiative equation (2.1a) and (2.1b) are coupled to the material energy balance equation that writes in its simplest form (see Gentile [11] or Pomraning [19]) as equation (2.1c) where \( \rho \) is the matter specific density, \( C_p \) is the specific heat capacity. In the particular case of the radiative equilibrium, we have \( E(T) = aT^4 \), \( \mathbf{F}(T) = 0 \), \( \mathbf{P}(T) = aT^4/3 \mathbf{I} \) with \( a = 8\pi^5k^4/15h^3c^3 \) and \( T_R = T \) where \( k \) is the Boltzmann constant and \( h \) is the Planck constant. The moments \( E \) and \( \mathbf{F} \) must verify that \( E \geq 0 \) and that \( f \leq 1 \) (flux limitation).

The radiative pressure is given by
\[
\mathbf{P} = \frac{1}{2} \left( (1 - \chi(f)) \mathbf{I} + (3\chi(f) - 1) \frac{\mathbf{F} \otimes \mathbf{F}}{||\mathbf{F}||^2} \right) E,
\]

where
\[
\chi(f) = \frac{3 + 4f^2}{5 + 2\xi},
\]
and \( \xi = \sqrt{4 - 3f^2} \). In the present work, the model uses non normalized variables. However, the normalized model can be easily deduced when setting \( c = 1 \) and \( a = 1 \).

Thanks to its construction based on the minimum entropy principle, we know that this system is hyperbolic symmetrizable (see [17]). Concerning the algebra of the hyperbolic system (2.1) the Jacobian matrix set in the \( x \)-direction reads as follows
\[
\begin{pmatrix}
0 & 0 & 0 & 0 \\
\frac{-f_xf_y}{f^2} & \frac{f_x}{f^2} \theta + \frac{f_y}{2f^2} & 0 & 0 \\
\frac{f_y}{f^2} & \frac{f_x}{f^2} \theta + \frac{f_y}{2f^2} & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix},
\]

where we have set \( \theta = 2 + 3f\chi' - 6\chi \). The eigenvalues of this matrix are given by
\[
\lambda^\pm = \frac{f_x}{\xi} \pm \frac{\sqrt{2} \sqrt{(\xi - 1)(\xi + 2)(2(\xi - 1)(\xi + 2) + 3f_y^2)}}{\sqrt{3}\xi(\xi + 2)},
\]
\[
\lambda^0 = \frac{(2 - \xi)f_x}{f^2}, \quad \lambda_{\text{stationary}} = 0.
\]

The eigenvalues of the Jacobian matrix in the \( y \)-direction are of the same form (with \( f_x \) replaced by \( f_y \)). We note that the eigenvalue \( \lambda^0 = c \mathbf{A}_x \) where \( \mathbf{A}_x \) is the \( x \)-component of the vector \( \mathbf{A} \) given by,
\[
\mathbf{A} = \frac{(2 - \xi)f}{f^2}.
\]

Moreover we can easily check that the characteristic fields associated with \( \lambda^\pm \) are genuinely nonlinear while the characteristic field associated with \( \lambda^0 \) is linearly degenerate. In radiative transfer the contact discontinuities play an important role connected with the shadow effect in transparent medium as we will see in the numerical experiments.
The dimensionless eigenvalues (i.e. $\lambda/c$) of the Jacobian matrix are given on figure 2.1 as functions of $f_x$ respectively for $f_y = 0$ and $f_y = \sqrt{3}/2$.

At equilibrium, i.e. for $f_x = f_y = 0$, the eigenvalues are $\lambda^\pm = \pm c/\sqrt{3}$, $\lambda^0 = 0$, which clearly illustrates the emission isotropy of the photons which prevails at this regime. On the other hand, in the case of extreme non-equilibrium (for instance when $f_x$ tends toward 1 and $f_y = 0$), both eigenvalues $\lambda^\pm$ tend towards $+c$ which describes that all photons move on the same direction (or that the underlying radiative intensity tends towards a Dirac which is called the free streaming regime).

For the sake of simplicity in the sequel, let us introduce the following useful notations (for the 2D $M_1$ model)

$$U = (E, F_x/c, F_y/c)^T, \quad F = (F_x, cP_{xx}, cP_{xy})^T, \quad G = (F_y, cP_{xy}, cP_{yy})^T. \quad (2.5)$$

A one dimension system can be obtained from (2.1) by assuming that all quantities are independent of $y$ and that $F_y = 0$. Then the eigenvalues of this $3 \times 3$ system are

$$\lambda^\pm = c \frac{f \sqrt{3} \pm 2(\xi - 1)}{\xi \sqrt{3}}, \quad \lambda^{\text{stationary}} = 0, \quad (2.6)$$

and coincides with the two extreme eigenvalues represented in figure 2.1. With some abuses in the 1D notations, we set

$$U = (E, F/c)^T, \quad F = (F, cP)^T, \quad (2.7)$$

where we have introduced $F = F_x$ in one space dimension.

It is well known that in the limit of an opaque medium ($\sigma$ tends to infinity), the matter temperature can be approximated by the solution of an asymptotic model called equilibrium diffusion equation (see [18, 19]). An important property of the $M_1$ system is that it recovers this equilibrium diffusion regime. Indeed, assuming that the opacity is large, we can rescale the $M_1$ system so that the Knudsen number $\epsilon$ appears in front of the time derivative term (long time approximation) and in the relaxation term (near equilibrium hypothesis):

$$\epsilon \partial_t E + \nabla \cdot F = \frac{\sigma c}{\epsilon} (aT^4 - E), \quad (2.8)$$

$$\epsilon \partial_t F + c \nabla \cdot P = -\frac{\sigma c}{\epsilon} \sigma F, \quad (2.9)$$

Fig. 2.1. Dimensionless eigenvalues of the Jacobian matrix.
\[ \epsilon \partial_t (\rho C_v T) = - \frac{\sigma c}{\epsilon} (aT^4 - E). \] (2.10)

An asymptotic expansion around \( \epsilon = 0 \) gives the usual near equilibrium behavior. If we set \( T = T_0 + \epsilon T_1 + \epsilon^2 T_2 + \ldots \), we get at the leading order, from equations (2.8) and (2.9), \( E_0 = aT_0^4 \) and \( F_0 = 0 \). At the next order, using equation (2.9) the flux can be written as \( F_1 = -\frac{\epsilon}{2} \nabla \cdot P_0 = -\frac{ac}{3\sigma} \nabla T_0^4 \). Finally, summing equations (2.8) and (2.10) at the following order leads to

\[ \partial_t (\rho C_v T_0 + aT_0^4) - \nabla \cdot \left( \frac{4c T_0^3}{3\sigma} \nabla T_0 \right) = 0, \] (2.11)

which is the equilibrium diffusion equation ([18]).

All important properties of the \( M_1 \) system are summarized in the following result (see [10])

**Theorem 2.1.** The radiative moment model \( M_1 \) has the following properties:

1. The radiative energy \( E \) remains positive: \( E \geq 0 \).
2. The normalized flux is limited: \( f \leq 1 \).
3. The set of admissible states \( \mathcal{A} = \{ \mathcal{U} = (E, F/c) / E \geq 0 \& f \leq 1 \} \) is a closed convex cone.
4. The system is hyperbolic and total energy \( E + \rho C_v T \) is conserved:

\[ \partial_t (E + \rho C_v T) + \nabla \cdot F = 0. \]

5. The \( M_1 \) system recovers the equilibrium diffusion regime as relaxation limit for large absorption coefficient.

**3. An HLLC approximate Riemann solver.** We propose to approximate the weak solutions of (2.1) when considering the well-known HLLC approximate Riemann solver (see Toro et al [22, 23], Batten et al [2] or Bouchut [5] to further details). This scheme is a modification of the initial HLL method, introduced by Harten, Lax and van Leer [14], to obtain an accurate scheme. Indeed, the HLLC method exactly captures the stationary contact waves while the pioneer HLL scheme cannot satisfy such a property.

For the sake of the clarity in the presentation, the HLLC scheme is firstly developed in one space dimension. The extension to higher space dimension will be proposed in the next section. As a consequence, in the present section, we deal with the following hyperbolic system:

\[
\begin{align*}
\partial_t E + \partial_x F &= c \sigma (aT^4 - E), \\
\frac{1}{\epsilon} \partial_t F + \partial_x (cP) &= -\sigma F, \\
\partial_t (\rho C_v T) &= -\sigma (aT^4 - E).
\end{align*}
\] (3.1)

This system turns out to be hyperbolic with relaxation source terms. To develop an HLLC solver for approximating the weak solutions of (3.1), we propose a strategy of term by term operator splitting. During the first step, we evolve in time (3.1), but neglecting the matter temperature relaxation terms. The prediction is thus governed by the following system:

\[
\begin{align*}
\partial_t E + \partial_x F &= 0, \\
\frac{1}{\epsilon} \partial_t F + \partial_x (cP) &= -\sigma F, \\
\partial_t (\rho C_v T) &= 0.
\end{align*}
\] (3.2)
The second step is devoted to introduce the matter temperature relaxation source terms \( \sigma(aT^4 - E) \). The resulting HLLC scheme will be shown to satisfy, at the discrete level, all the properties stated in theorem 2.1.

### 3.1. The first step (a prediction)

The weak solutions of the system (3.2) are approximated involving an HLLC Riemann solver. Following the ideas introduced by Harten, Lax and van Leer [14] and extended by Toro [22] (see also [2, 5, 23]), we propose to put forward an approximate Riemann solver according to system (3.2).

#### 3.1.1. The system to be approximated

After the recent work of Bouchut [5] (and reference therein), a relevant interpretation of the relaxation source terms is proposed when introducing the variable \( \Sigma(x) \) defined as follows:

\[
\sigma(x) = \partial_x \Sigma(x),
\]

(3.3)

to write (3.2) in the following form:

\[
\begin{align*}
\partial_t E + \partial_x F &= 0, \\
\frac{1}{c} \partial_t F + \partial_x (cP) &= -F \partial_x \Sigma, \\
\partial_t (\rho C_v T) &= 0, \\
\partial_t \Sigma &= 0.
\end{align*}
\]

(3.4)

Since \( \Sigma \) does not depend on the time variable, the system is completed by

\[
\partial_t \Sigma = 0.
\]

(3.5)

Now, let us note that the system (3.4)-(3.5) can be rewritten in conservation form. Indeed, we have: \( F \partial_x \Sigma = \partial_x (F \Sigma) + \partial_t (\Sigma E) \). Hence, the system (3.4)-(3.5) rewrites as follows:

\[
\begin{align*}
\partial_t E + \partial_x F &= 0, \\
\partial_t \left( \frac{1}{c} F + \Sigma E \right) + \partial_x (cP + E) &= 0, \\
\partial_t (\rho C_v T) &= 0, \\
\partial_t \Sigma &= 0.
\end{align*}
\]

(3.6)

To shorten the notations, the system (3.6) is given in the following form:

\[
\partial_t \mathcal{V} + \partial_x \mathcal{H}(\mathcal{V}) = 0,
\]

(3.7)

where we have set

\[
\mathcal{V} = \left( E, \frac{1}{c} F + \Sigma E, \rho C_v T, \Sigma \right)^T \quad \text{and} \quad \mathcal{H}(\mathcal{V}) = \left( F, cP + \Sigma E, 0, 0 \right)^T.
\]

An HLLC scheme is now considered to approximate the weak solutions of (3.6).

### 3.1.2. Definition of the HLLC approximate Riemann solver

To approximate the Riemann solution arising with system (3.6), we turn considering an approximate solver with the following structure (see also figure 3.1):

\[
\mathcal{V}(x, t) = \begin{cases} 
\mathcal{V}_L & \text{if } \frac{e}{T} < b_L, \\
\mathcal{V}^L & \text{if } b_L < \frac{e}{T} < 0, \\
\mathcal{V}_R & \text{if } 0 < \frac{e}{T} < b_R, \\
\mathcal{V}_R & \text{if } \frac{e}{T} > b_R.
\end{cases}
\]
The wavespeeds \( b_L < 0 < b_R \) will be estimated later according to additional stability conditions.

Let us note from now on that the initial HLLC scheme considers a middle wave with velocity \( b^* \) (see Batten et al [2] or Toro [22]). In the present work, the middle wave is associated with the trivial contact wave with a vanished velocity, involved by the equations on \( \rho C_v T \) and \( \Sigma \). In this sense, we have imposed \( b^* = 0 \). Now, we have to determine the approximate states \( \mathcal{V}_L^* \) and \( \mathcal{V}_R^* \) in the star region and the corresponding flux functions \( \mathcal{H}_L \) and \( \mathcal{H}_R \). To access such an issue, several assumptions will be done on the choice of the linearizations. As usual, we have set

\[
\mathcal{H}_L = \mathcal{H}(V_L) \quad \text{and} \quad \mathcal{H}_R = \mathcal{H}(V_R),
\]

but we do not impose \( \mathcal{H}_{L,R} = \mathcal{H}(V_{L,R}^*) \). To evaluate \( \mathcal{V}_{L,R}^* \) and \( \mathcal{H}_{L,R} \), we apply the Rankine-Hugoniot conditions (see [2, 22]) across each of the waves of speed \( b_L \) and \( b_R \):

\[
\begin{align*}
\mathcal{H}_L - \mathcal{H}_L &= b_L (\mathcal{V}_L^* - \mathcal{V}_L), \\
\mathcal{H}_R - \mathcal{H}_R &= b_R (\mathcal{V}_R^* - \mathcal{V}_R).
\end{align*}
\]

To complete the system, we impose supplementary conditions on the approximate Riemann solver. First, let us emphasize that the quantities \( F \) and \( \mathcal{V} \) are exactly shown to be continuous across the stationary contact wave involved into exact Riemann problem associated with (3.6). As a consequence, we propose to consider the following formulas:

\[
\begin{align*}
\check{F}_L &= \check{F}_R = \check{F}, \\
\check{F}_L^* &= \check{F}_R^* = F^*, \\
cP_L^* + \check{\Sigma}_L \check{F}_L &= cP_R^* + \check{\Sigma}_R \check{F}_R, \\
cP_L + \Sigma_L \check{F}_L^* &= cP_R + \Sigma_R \check{F}_R^*.
\end{align*}
\]

Next, we note that the exact Riemann solution of (3.6) satisfies \( \Sigma(x,t) = \Sigma_L \) if \( x < 0 \) and \( \Sigma(x,t) = \Sigma_R \) if \( x > 0 \). Then, we enforce the approximate Riemann solver to satisfy:

\[
\check{\Sigma}_L = \Sigma_L \quad \text{and} \quad \check{\Sigma}_R = \Sigma_R.
\]
Extending ideas introduced in [6], we impose the following linearization satisfied by the star-pressure:

\[ P_L^* = -\frac{b_L b_R}{c^2} E_L^* \quad \text{and} \quad P_R^* = -\frac{b_L b_R}{c^2} E_R^*. \]

(3.15)

The HLLE approximate Riemann solver is now fully defined since he unknowns \( V_{L,R}^* \)
and \( \hat{\mathcal{H}}_{L,R} \) are solutions of the system (3.8)–(3.15).

### 3.1.3. Some notations.

Before we solve \( V_{L,R}^* \) and \( \hat{\mathcal{H}}_{L,R} \), let us introduce several
notations, useful in the sequel. First, we set

\[ \Sigma_R - \Sigma_L = \sigma \Delta x. \]

(3.16)

This notation is in agreement with the exact definition of \( \Sigma \) given by (3.3), and it will
turn out to be useful to clarify the writing of the final numerical scheme.

Next, we introduce a parameter \( \alpha \) defined as follows:

\[ \alpha = \frac{b_R - b_L}{b_R - b_L + \sigma \Delta x}. \]

(3.17)

This parameter will play a crucial role since it will define the transport region:

\[ \alpha \to 1 \quad \text{as} \quad \sigma \to 0, \]

(3.18)

and the asymptotic diffusion limit

\[ \alpha \to 0 \quad \text{as} \quad \sigma \to +\infty. \]

(3.19)

The last notations we introduce are devoted to the standard HLL Riemann solver (see
[5, 14, 22]) when considering the system (3.6) but for an uniform vanishing \( \sigma \):

\[ \begin{cases}
\partial_t E + \partial_x F = 0, \\
\frac{1}{\epsilon} \partial_t F + \partial_x (\epsilon P) = 0, \\
\partial_t (\rho C_v T) = 0.
\end{cases} \]

(3.20)

Indeed, in the case of an HLL Riemann solver, the star region is made of a constant
single state defined as follows (see [22] to further details, and also figure 3.1):

\[ E_{*,\text{HLL}}^* = \frac{b_R E_R - b_L E_L - (F_R - F_L)}{b_R - b_L}, \]

(3.21)

\[ F_{*,\text{HLL}}^* = \frac{b_R F_R - b_L F_L - c^2 (P_R - P_L)}{b_R - b_L}. \]

(3.22)

The corresponding flux functions read as follows:

\[ \tilde{F}_{\text{HLL}} = \frac{b_R F_L - b_L F_R - b_L b_R (E_L - E_R)}{b_R - b_L}, \]

(3.23)

\[ \tilde{P}_{\text{HLL}} = \frac{b_R P_L - b_L P_R - b_L b_R (F_L - F_R)}{b_R - b_L}. \]

(3.24)

Once again, let us emphasize that the notations \( E_{*,\text{HLL}}, F_{*,\text{HLL}}, \tilde{F}_{\text{HLL}} \)
and \( \tilde{P}_{\text{HLL}} \) will not enter the definition of our HLLE scheme but they will short the formulas
involved in the sequel of the paper.
3.1.4. Characterization of the approximate Riemann solver. Involving the above notations, the system (3.8)-(3.15) is solved to compute the unknowns \( \mathcal{V}_{L,R}^* \) and \( \mathcal{H}_{L,R} \). The following statement gives this expected solution and thus the full characterization of the approximate Riemann solver is achieved:

**Lemma 3.1.** Let \( \mathcal{V}_{L,R}^* \) and \( \mathcal{H}_{L,R} \) be solution of the system (3.8)-(3.15). Let us set

\[
E_{L,R}^* = E_{L,R} - \frac{F_{L,R}}{b_{L,R}},
\]

(3.25)

Then we have

\[
E_{L,R}^* = \alpha E^{*\cdot HLL} + (1 - \alpha) E_{L,R}^0,
\]

(3.26)

\[
F^* = \alpha F^{*\cdot HLL},
\]

(3.27)

\[
\Sigma_{L,R}^* = \Sigma_{L,R},
\]

(3.28)

\[
(\rho C_v T)_{L,R}^* = (\rho C_v T)_{L,R},
\]

(3.29)

and

\[
\bar{F} = \alpha \bar{F}^{HLL},
\]

(3.30)

\[
P_{L,R} = \alpha P^{HLL} + (1 - \alpha) \left( P_{L,R} - \frac{b_{L,R}}{c^2} F_{L,R} \right).
\]

(3.31)

**Proof.** First, from (3.8) and (3.9), we immediately deduce that

\[
\Sigma_{L}^* = \Sigma_{L} \quad \text{and} \quad \Sigma_{R}^* = \Sigma_{R},
\]

(3.32)

\[
(\rho C_v T)_{L}^* = (\rho C_v T)_{L} \quad \text{and} \quad (\rho C_v T)_{R}^* = (\rho C_v T)_{R}.
\]

(3.33)

Next, we argue (3.8)-(3.9) to write

\[
\begin{cases}
\bar{F} - F_L = b_L (E_L^* - E_L), \\
\bar{F} - F_R = b_R (E_R^* - E_R),
\end{cases}
\]

and then obtain

\[
(b_R - b_L) \bar{F} - b_R F_L + b_L F_R = b_L b_R (E_L^* - E_R^*) - b_L b_R (E_L - E_R).
\]

(3.34)

Moreover, from the linearization (3.15), we deduce

\[
c^2 P_L^* - c^2 P_R^* = -b_L b_R (E_L^* - E_R^*).
\]

(3.35)

When involving (3.12), we have

\[
c^2 P_L^* - c^2 P_R^* = c (\Sigma_R - \Sigma_L) \bar{F},
\]

\[
= c \sigma \Delta x \bar{F},
\]

(3.36)

to obtain

\[
-b_L b_R (E_L^* - E_R^*) = c \sigma \Delta x \bar{F}.
\]

(3.37)

We substitute this above identity into (3.34) to write

\[
(b_R - b_L + c \sigma \Delta x) \bar{F} = b_R F_L - b_L F_R - b_L b_R (E_L - E_R).
\]
Involving (3.17) and (3.23), we obtain the expected formula (3.30) to define $\tilde{F}$.

As soon as $\tilde{F}$ is known, we can compute $V^*_{L,R}$. First, we solve $E^*_L$ while $E^*_R$ is obtained involving a similar computation. The Rankine-Hugoniot relation (3.8) gives:

$$b_L(E^*_L - E_L) = \tilde{F} - F_L,$$

$$= \alpha F^*_{HLL} - F_L,$$

to obtain

$$E^*_L = \frac{\alpha}{b_L}(\tilde{F}^*_{HLL} - F_L + b_L E_L) + (1 - \alpha) \left( E_L - \frac{F_L}{b_L} \right).$$

In addition, from (3.21) and (3.23), we easily deduce:

$$b_L E^*_{L,HLL} = \tilde{F}^*_{HLL} - F_L + b_L E_L,$$

to write

$$E^*_L = \alpha E^*_{L,HLL} + (1 - \alpha) E^*_L.$$  \hspace{1cm} (3.38)

Similarly, we have

$$E^*_R = \alpha E^*_{R,HLL} + (1 - \alpha) E^*_R.$$  \hspace{1cm} (3.39)

The state vectors $V^*_L$ and $V^*_R$ will be solved as soon as $F^*$ will be determined. To access such an issue, once again the relations (3.8) and (3.9) are considered to write:

$$b_L \left( \frac{F^*}{c} + \Sigma^*_L E^*_L \right) - \left( \frac{F_L}{c} + \Sigma L E_L \right) = \left( c \tilde{P}_L + \Sigma L \tilde{F}_L \right) - \left( c P_L + \Sigma L F_L \right),$$

$$b_R \left( \frac{F^*}{c} + \Sigma^*_R E^*_R \right) - \left( \frac{F_R}{c} + \Sigma R E_R \right) = \left( c \tilde{P}_R + \Sigma R \tilde{F}_R \right) - \left( c P_R + \Sigma R F_R \right).$$

Involving (3.11), (3.15) and (3.28), we rewrite these relations as follows:

$$\begin{cases}
    b_L(F^* - F_L) + b_L \Sigma L (E^*_L - E_L) = c(\tilde{P}_L - P_L) + \Sigma L (\tilde{F} - F_L), \\
    b_R(F^* - F_R) + b_R \Sigma R (E^*_R - E_R) = c(\tilde{P}_R - P_R) + \Sigma R (\tilde{F} - F_R). 
\end{cases}$$ \hspace{1cm} (3.40)

Since

$$\begin{cases}
    b_L(E^*_L - E_L) = \tilde{F} - F_L, \\
    b_R(E^*_R - E_R) = \tilde{F} - F_R,
\end{cases}$$ \hspace{1cm} (3.41)

we deduce from (3.40) the following identity:

$$(b_R - b_L)F^* = c^2(\tilde{P}_R - \tilde{P}_L) - c^2(P_R - P_L) + b_R F_R - b_L F_R.$$ \hspace{1cm} (3.42)

We involve (3.13) to write

$$c^2(\tilde{P}_R - \tilde{P}_L) = -c \sigma \Delta x F^*,$$

and then we obtain

$$(b_R - b_L + c \sigma \Delta x)F^* = b_R F_R - b_L F_L - c^2(P_R - P_L).$$
From (3.22), we obtain the equation (3.27) to define $F^*$, and the computations to estimate $V^*_L$ and $V^*_R$ are achieved.

Now, to complete the determination of $\tilde{H}_L$ and $\tilde{H}_R$, we have just to compute $\tilde{P}_L$ and $\tilde{P}_R$. We plug (3.41) into (3.40) to write

$$\tilde{P}_L = P_L + \frac{b_L}{c^2}(F^* - F_L),$$
$$\tilde{P}_R = P_R + \frac{b_R}{c^2}(F^* - F_R).$$

Involving (3.24), we immediately obtain the expected identity (3.31) and the proof is thus completed. □

3.1.5. Main properties of the approximate Riemann solver. To achieve the analysis of the star region, introduced in the approximate Riemann solver (see figure 3.1), we exhibit relevant conditions to enforce stability properties. With the notations introduced in (2.7), we define

$$U^*_{L,R} = \left( \begin{array}{c} E^*_{L,R} \\ F^*_{L,R} \end{array} \right).$$

We have to enforce that the approximate Riemann solver satisfies $U^*_{L,R} \in \mathcal{A}$ when $\mathcal{A}$, defined in theorem 2.1, is the set of the admissible states.

Now, involving the definition of $E^*_{L,R}$, given by (3.26), and $F^*$, given by (3.27), we can write

$$U^*_{L,R} = aU^{*,HLL} + (1 - a)U^0_{L,R},$$

where

$$U^{*,HLL} = \left( \begin{array}{c} E^{*,HLL}_{L,R} \\ F^{*,HLL}_{L,R} / c \end{array} \right) \quad \text{and} \quad U^0_{L,R} = \left( \begin{array}{c} E^0_{L,R} \\ 0 \end{array} \right).$$

Since $\alpha$, defined by (3.17), belongs to $[0,1]$, and since $\mathcal{A}$ is a convex set, we have just to establish that $U^{*,HLL}$ and $U^0_{L,R}$ belong to $\mathcal{A}$ in order to enforce $U^*_{L,R} \in \mathcal{A}$. In the following result, as long as the velocities $b_L$ and $b_R$ satisfy relevant conditions, we show that $U^*_{L,R}$ are in $\mathcal{A}$:

**Lemma 3.2.** Let us define

$$f_L = \frac{F_L}{cE_L} \quad \text{and} \quad f_R = \frac{F_R}{cE_R}. \quad (3.43)$$

Assume

$$b_L \leq \min \left( 0, cf_L, \frac{f_L - \chi_L}{1 - f_L}, \frac{f_L + \chi_L}{1 + f_L} \right), \quad (3.44)$$
$$b_R \geq \max \left( 0, cf_R, \frac{f_R - \chi_R}{1 - f_R}, \frac{f_R + \chi_R}{1 + f_R} \right), \quad (3.45)$$

where $\chi_{L,R} = \chi(f_{L,R})$ with the function $\chi$ defined by (2.3). Then $U^{*,HLL}$ and $U^0_{L,R}$ are in $\mathcal{A}$. As a consequence, $U^*_{L,R} \in \mathcal{A}$.

**Proof.** To obtain $U^0_{L,R}$ in $\mathcal{A}$, we have just to enforce:

$$E^0_L = E_L - \frac{F_L}{b_L} \geq 0 \quad \text{and} \quad E^0_R = E_R - \frac{F_R}{b_R} \geq 0.$$
these conditions are easily see to be verified as long as (3.44) and (3.45) are satisfied. Concerning \( U^{*,HLL} \), we show that
\[
E^{*,HLL} > 0 \quad \text{and} \quad -cE^{*,HLL} < F^{*,HLL} < cE^{*,HLL},
\]
under the conditions (3.44) and (3.45). First, we write
\[
E^{*,HLL} = \frac{b_R}{b_R - b_L} E_R^0 + \frac{-b_L}{b_R - b_L} E_L^0.
\]
Since \( E_{L,R}^0 > 0 \), we immediately deduce that \( E^{*,HLL} > 0 \).

Now, concerning the flux limitation, we rewrite the condition \( F^{*,HLL} < cE^{*,HLL} \) in the following form:
\[
\left( b_R \left( F_R - \frac{c^2}{b_R} P_R \right) - cb_R E_R + cF_R \right) - \left( b_L \left( F_L - \frac{c^2}{b_L} P_L \right) - cb_L E_L + cF_L \right) < 0.
\]
It is thus clear that the expected inequality \( F^{*,HLL} < cE^{*,HLL} \) holds as soon as we have
\[
\begin{cases}
  b_R \left( F_R - \frac{c^2}{b_R} P_R \right) - cb_R E_R + cF_R < 0, \\
  b_L \left( F_L - \frac{c^2}{b_L} P_L \right) - cb_L E_L + cF_L > 0.
\end{cases}
\]
Involving (3.43) and (2.2), we rewrite the two above inequalities in the following form:
\[
\begin{align*}
  b_R &> c \frac{f_R - \chi_R}{1 - f_R} \quad \text{and} \quad b_L < c \frac{f_L - \chi_L}{1 - f_L},
\end{align*}
\]
Arguing a similar computation, we ensure that the inequality \( F^{*,HLL} > -cE^{*,HLL} \) holds as long as we have
\[
\begin{align*}
  b_R &> c \frac{f_R + \chi_R}{1 + f_R} \quad \text{and} \quad b_L < c \frac{f_L + \chi_L}{1 + f_L}.
\end{align*}
\]
The proof is thus achieved. \( \square \)

3.1.6. The HLLE scheme. The above approximate Riemann solver is used to propose a relevant numerical scheme for approximating the weak solutions of (3.4). We consider a structured mesh defined by the cells \( I_i = [x_{i-1/2}, x_{i+1/2}] \) with
\[
x_{i+1/2} = x_i + \frac{\Delta x}{2}, \quad i \in \mathbb{Z},
\]
where \( \Delta x \) is the spatial cell width. Under the CFL like condition:
\[
\frac{\Delta t}{\Delta x} \max_{i \in \mathbb{Z}} \left( |b_{L,i+1/2}^n|, |b_{R,i-1/2}^n| \right) \leq \frac{1}{2},
\]
we set, at each cell interface \( x_{i+1/2} \), the approximate Riemann solver where \( \mathcal{V}_L \) and \( \mathcal{V}_R \) are substituted by \( \mathcal{V}^n_{i+1} \) and \( \mathcal{V}^n_{i+1} \).

The CFL condition ensures that all the Riemann solvers do not interact (see figure 3.2) where the two extreme wavespeeds are estimated involving the exact eigenvalues.
(2.6). After the work of Batten et al [2] (see also Toro et al [22, 23] and Bouchut [5]), we propose to consider:

\[
\begin{align*}
    b_L^{i+\frac{1}{2}} &\leq \min \left( 0, cf_i^n, c \frac{f_i^n - \chi_i^n}{1 - f_i^n}, c \frac{f_i^n + \chi_i^n}{1 + f_i^n}, \lambda^-(U_i^n) \right), \\
    b_R^{i+\frac{1}{2}} &\geq \max \left( 0, cf_i^n, c \frac{f_i^n - \chi_i^n}{1 - f_i^n}, c \frac{f_i^n + \chi_i^n}{1 + f_i^n}, \lambda^+(U_i^n) \right),
\end{align*}
\]

with

\[
f_i^n = \frac{F_i^n}{cE_i^n} \quad \text{and} \quad \chi_i^n = \chi(f_i^n).
\]

We set \(V(t, x^n + \Delta t)\) the approximate solution at time \(t^n + \Delta t\), made of the juxtaposition of the non-interacting approximate Riemann solvers.

Next, the projection of these solutions on the piecewise constant functions gives:

\[
\begin{pmatrix}
    E_i^{n+1} \\
    F_i^n/c \\
    (\rho E_i T)_{i+1}^{n+1}
\end{pmatrix} = \frac{1}{\Delta x} \int_{x_i - \frac{1}{2}}^{x_i + \frac{1}{2}} \begin{pmatrix}
    E_i^h(x, t^n + \Delta t) \\
    F_i^h(x, t^n + \Delta t)/c \\
    (\rho E_i T)^h_i(x, t^n + \Delta t)
\end{pmatrix} dx.
\]

After an usual and easy computation, we obtain

\[
\begin{align*}
    E_i^{n+1} &= E_i^n - \frac{\Delta t}{\Delta x} \left( \alpha_{i+\frac{1}{2}} \tilde{F}_{i+\frac{1}{2}}^{HLL} - \alpha_{i-\frac{1}{2}} \tilde{F}_{i-\frac{1}{2}}^{HLL} \right), \\
    F_i^{n+1} &= F_i^n - \frac{\Delta t}{\Delta x} c^2 \left( \alpha_{i+\frac{1}{2}} \tilde{F}_{i+\frac{1}{2}}^{HLL} - \alpha_{i-\frac{1}{2}} \tilde{F}_{i-\frac{1}{2}}^{HLL} + \left( \alpha_{i+\frac{1}{2}} - \alpha_{i-\frac{1}{2}} \right) F_i^n \right) + \\
    &\quad \frac{\Delta t}{\Delta x} \left( (1 - \alpha_{i+\frac{1}{2}}) b_L^{i+\frac{1}{2}} - (1 - \alpha_{i-\frac{1}{2}}) b_R^{i-\frac{1}{2}} \right) F_i^n, \\
    (\rho E_i T)_{i+1}^{n+1} &= (\rho E_i T)_{i+1}^n
\end{align*}
\]

At this level of the scheme, we have proposed a predictor step which will be seen to preserve the positiveness of the energy \(E_i^{n+1}\) and the flux limitation (see section 3.3).

### 3.2. The second step (a correction)

The above numerical scheme \((3.50)\) must be corrected to propose a suitable discrete form of the matter temperature relaxation source terms \(c\sqrt{\alpha} (aT^4 - E)\). To access such an issue, we propose to modify the star region states, \(V_{L,R}\), introduced in the approximate Riemann solver (see figure 3.1), according to the relaxation source terms. Put in other words, the state vectors
\( \mathcal{V}_{L,R}^* \) and the corresponding flux function \( \mathcal{H}_{L,R} \) must be corrected to satisfy a suitable approximation of

\[
\begin{align*}
\partial_t E &= c\sigma(aT^4 - E), \\
\partial_t F &= 0, \\
\partial_t (\rho C_v T) &= -c\sigma(aT^4 - E).
\end{align*}
\]

The corrected results will be denoted \( \mathcal{V}_{L,R}^{*,HLLC} \) and \( \mathcal{H}_{L,R}^{HLLC} \). They will be defined as follows:

\[
\begin{align*}
E_{L,R}^{*,HLLC} - E_{L,R}^* &= (1 - \alpha) \left( a \left( T_{L,R}^{*,HLLC} \right)^4 - E_{L,R}^0 \right), \\
F_{L,R}^{*,HLLC} - F^* &= 0, \\
\rho C_v \left( T_{L,R}^{*,HLLC} - T_{L,R}^* \right) &= -(1 - \alpha) \left( a \left( T_{L,R}^{*,HLLC} \right)^4 - E_{L,R}^0 \right),
\end{align*}
\]

where \( \alpha \) is defined by (3.17), \( E_{L,R}^* \) is given by (3.26), \( F^* \) is given by (3.27) and \( E_{L,R}^0 \) is given by (3.25). We easily deduce the following corrected approximation for \( E \) and \( F \):

\[
\begin{align*}
E_{L,R}^{*,HLLC} &= \alpha E_{L,R}^{*,HLL} + (1 - \alpha)a \left( T_{L,R}^{*,HLLC} \right)^4, \\
F_{L,R}^{*,HLLC} &= \alpha F_{L,R}^{*,HLL}.
\end{align*}
\]

Arguing the definition (2.7), we write for short

\[
\mathcal{U}_{L,R}^{*,HLLC} = \alpha \mathcal{U}_{L,R}^{*,HLL} + (1 - \alpha) \mathcal{U}_{L,R}^0,
\]

where \( \mathcal{U}_{L,R}^0 \) corresponds to the asymptotic state and it is defined as follows:

\[
\mathcal{U}_{L,R}^0 = \left( \begin{array}{c}
a \\ 0 \end{array} \right) \left( T_{L,R}^{*,HLLC} \right)^4 ,
\]

with \( T_{L,R}^{*,HLLC} \) defined in the following result:

**Lemma 3.3.** The matter temperature \( T_{L,R}^{*,HLLC} \) is the unique solution of the following equation:

\[
\rho C_v T_{L,R}^{*,HLLC} + (1 - \alpha)a(T_{L,R}^{*,HLLC})^4 = \rho C_v T_{L,R} + (1 - \alpha)E_{L,R}^0.
\]

In addition, \( T_{L,R}^{*,HLLC} \) is positive.

The proof of this result turns out to be obvious and it is omitted. Now, we can establish that the corrected states \( \mathcal{U}_{L,R}^{*,HLLC} \) belong to \( \mathcal{A} \).

**Lemma 3.4.** Let us consider the assumptions stated in lemma 3.2. Then, \( \mathcal{U}_{L,R}^{*,HLLC} \), defined by (3.53), belongs to \( \mathcal{A} \).

**Proof.** From lemma 3.2, we have \( \mathcal{U}_{L,R}^{*,HLL} \in \mathcal{A} \). In addition, after the positiveness of \( T_{L,R}^{*,HLLC} \), we easily deduce that

\[
\left( \begin{array}{c}
a \\ 0 \end{array} \right) \left( T_{L,R}^{*,HLLC} \right)^4 \in \mathcal{A}.
\]
Now, applying the convex property of $A$, we immediately obtain the expected result.

To conclude the determination of the corrected states, $V^{*, HLLC}_{L,R}$, we specify the asymptotic behavior of the approximate Riemann solver. Indeed, let us assume that $c \sigma$ goes to zero (or equivalently, $\alpha$ tends to 1). In this case, we typically enter the regime of pure transport equations. From (3.51), (3.52) and (3.55), we have for such a limit:

$$
\begin{align*}
E^{*, HLLC}_{L,R} & \to E^{*, HLL}_{L,R}, \\
F^{*, HLLC}_{L,R} & \to F^{*, HLL}_{L,R}, \\
T^{*, HLLC}_{L,R} & \to T_{L,R}.
\end{align*}
$$

As expected, the approximate Riemann solver coincides with the standard Riemann solver involved when considering an HLLC scheme to approximate solutions of (3.20).

Now, we turn considering the asymptotic behavior as long as $c \sigma$ goes to infinity, or equivalently assume that $\alpha$ tends to 0. In this case, we obtain the following limit:

$$
\begin{align*}
E^{*, HLLC}_{L,R} & \to \alpha \left( T^{*, HLLC}_{L,R} \right)^4, \\
F^{*, HLLC}_{L,R} & \to 0,
\end{align*}
$$

to coincide with the asymptotic diffusion regime.

To complete the determination of the star region, we have to solve the resulting flux function $H^{HLLC}_{L,R}$. It will be done as soon as $E^{*, HLLC}_{L,R}$ and $F^{*, HLLC}_{L,R}$ should be evaluated. To access such an issue, once again, we consider the Rankine-Hugoniot relations (3.8) and (3.9). First, we have

$$
\tilde{E}^{HLLC}_{L,R} = F_{L,R} + b_{L,R} \left( E^{*, HLLC}_{L,R} - E_{L,R} \right).$$

Involving (3.51), we obtain

$$
\tilde{F}^{HLLC}_{L,R} = \alpha \tilde{F}^{HLL} + (1 - \alpha) b_{L,R} \left( E^{*, HLLC}_{L,R} - E_{L,R} \right). 
$$

Similarly, from (3.8) and (3.9), we deduce

$$
c^2 \tilde{P}^{HLLC}_{L,R} = c^2 P_{L,R} + b_{L,R} \left( F^{*, HLLC}_{L,R} - F_{L,R} \right),$$

to write when considering (3.52):

$$
c^2 \tilde{P}^{HLLC}_{L,R} = \alpha c^2 \tilde{P}^{HLL} + (1 - \alpha) \left( c^2 P_{L,R} - b_{L,R} F_{L,R} \right).$$

To conclude the description of the approximate Riemann solver, let us note that the corresponding flux function $\tilde{\mathcal{F}}^{HLLC}_{L,R}$, associated with $U^{*, HLLC}_{L,R}$, reads as follows:

$$
\tilde{\mathcal{F}}^{HLLC}_{L,R} = \alpha \tilde{\mathcal{F}}^{HLL} + (1 - \alpha) S^a_{L,R},
$$

where $S^a_{L,R}$ is given by

$$
S^a_{L,R} = b_{L,R} \left( U^a_{L,R} - U^0_{L,R} \right),
$$

and

$$
U^0_{L,R} = U_{L,R} - \frac{1}{b_{L,R}} \mathcal{F}_{L,R}.
$$
Of course, in a practical point of view, the equivalent formulas (3.56) and (3.57) are preferred. In fact, (3.58) and (3.59) will play a useful role for the 2D extension of the scheme. In addition, we note from now on that $\mathcal{F}^{HLL}$ will participate to the discretization of the transport part while the discrete form of the relaxation source terms inherit from $\mathcal{S}^0_{L,R}$. We add that the jump relations applied to the matter temperature reads

$$
\mathcal{S}^0_{L,R} = b_{L,R} \rho C_v \left( T_{L,R}^{*,HLLC} - T_{L,R} \right),
$$

$$
= -b_{L,R}(1 - \alpha) \left( a \left( T_{L,R}^{*,HLLC} \right)^4 - E_{L,R}^0 \right). \tag{3.61}
$$

Actually, this relation play a central role in the discrete form of source terms involved in the matter temperature evolution equation (see equation (3.62)).

Now, involving the corrected approximate Riemann solver, defined by (3.51), (3.52) and (3.55), we describe the expected HLLC scheme to approximate the solutions of system (3.1). We consider the same strategy as used in the prediction step (see figure 3.3).

![Fig. 3.3. Structure of the approximate Riemann solver for the corrected HLLC scheme.](image)

We adopt the CFL restriction (3.46). The approximate Riemann solver, at time $t^n + \Delta t$, is projected on the piecewise constant functions following (3.49). After the computations, the achieved scheme reads as follows:

$$
E_i^{n+1} = E_i^n - \frac{\Delta t}{\Delta x} \left( \alpha_{i+\frac{1}{2}} \tilde{F}_{i+\frac{1}{2}}^{HLL} - \alpha_{i-\frac{1}{2}} \tilde{F}_{i-\frac{1}{2}}^{HLL} \right)
$$

$$
- \frac{\Delta t}{\Delta x} \left( (1 - \alpha_{i+\frac{1}{2}}) b_{i+\frac{1}{2}}^{i+\frac{1}{2}} \left( a \left( T_{L,R}^{*,HLLC} \right)^4 - \left( E_i^n - \frac{E_i^n}{b_{i+\frac{1}{2}}^{i+\frac{1}{2}}} \right) \right) \right),
$$

$$
- (1 - \alpha_{i-\frac{1}{2}}) b_{i-\frac{1}{2}}^{i-\frac{1}{2}} \left( a \left( T_{L,R}^{*,HLLC} \right)^4 - \left( E_i^n - \frac{E_i^n}{b_{i-\frac{1}{2}}^{i-\frac{1}{2}}} \right) \right) \right), \tag{3.62a}
$$

$$
F_i^{n+1} = F_i^n - \frac{\Delta t}{\Delta x} \left( \alpha_{i+\frac{1}{2}} \tilde{F}_{i+\frac{1}{2}}^{HLL} - \alpha_{i-\frac{1}{2}} \tilde{F}_{i-\frac{1}{2}}^{HLL} + (\alpha_{i+\frac{1}{2}} - \alpha_{i-\frac{1}{2}}) \tilde{P}_i^n \right) +
$$

$$
\frac{\Delta t}{\Delta x} \left( (1 - \alpha_{i+\frac{1}{2}}) b_{i+\frac{1}{2}}^{i+\frac{1}{2}} \left( (1 - \alpha_{i+\frac{1}{2}}) b_{i+\frac{1}{2}}^{i+\frac{1}{2}} - (1 - \alpha_{i-\frac{1}{2}}) b_{i-\frac{1}{2}}^{i-\frac{1}{2}} \right) \right) F_i^n, \tag{3.62b}
$$

$$
(\rho C_v T)^{n+1} = (\rho C_v T)_i^n + \frac{\Delta t}{\Delta x} \left( (1 - \alpha_{i+\frac{1}{2}}) b_{i+\frac{1}{2}}^{i+\frac{1}{2}} \left( a \left( T_{L,R}^{*,HLLC} \right)^4 - \left( E_i^n - \frac{E_i^n}{b_{i+\frac{1}{2}}^{i+\frac{1}{2}}} \right) \right) \right)
$$

$$
- (1 - \alpha_{i-\frac{1}{2}}) b_{i-\frac{1}{2}}^{i-\frac{1}{2}} \left( a \left( T_{L,R}^{*,HLLC} \right)^4 - \left( E_i^n - \frac{E_i^n}{b_{i-\frac{1}{2}}^{i-\frac{1}{2}}} \right) \right) \right). \tag{3.62c}
$$
3.3. The main properties. We turn establishing the main properties satisfied by the approximate solutions. These properties will emphasize that the scheme is relevant. We give the discrete version of theorem 2.1. In a first result, the positiveness of the radiative energy, the flux limitation and the conservation of the total energy are proved. Next, a second statement shows that the considered scheme satisfies the expected asymptotic limit as long as the parameter \( \sigma \) goes to infinity.

**Theorem 3.5.** Let \( U_i^n \) be in \( A \) and \( T_i^n \) be positive. Assume the CFL restriction (3.46) where the wavespeeds \( b_R^{i+\frac{1}{2}} \) and \( b_L^{i-\frac{1}{2}} \) are given by (3.47)-(3.48). The updated approximate solution \( U_i^{n+1} \), defined by (3.62), satisfies the following properties:

1. the radiative energy \( E_i^{n+1} \) remains positive,
2. the normalized flux is limited: \( |f_i^{n+1}| \leq 1 \),
3. the total energy \( (E + \rho C_v T_i)^{n+1} \) is conserved.

**Proof.** The two first properties are proved when establishing that \( U_i^{n+1} \) belongs to \( A \). By definition of the scheme (3.62), \( U_i^{n+1} \) is obtained after considering the projection (3.49) of the approximate Riemann solver on the piecewise constant function:

\[
U_i^{n+1} = \frac{1}{\Delta x} \int_{x_{i-1/2}}^{x_{i+1/2}} U^h(x, t^{n+1}) dx,
\]

\[
= b_R^{i+\frac{1}{2}} \frac{\Delta t}{\Delta x} U_{R, i-\frac{1}{2}}^{n, \text{HLLC}} + \left( 1 - (b_R^{i+\frac{1}{2}} - b_L^{i-\frac{1}{2}}) \frac{\Delta t}{\Delta x} \right) U_i^n - b_L^{i-\frac{1}{2}} \frac{\Delta t}{\Delta x} U_{L, i+\frac{1}{2}}^{n, \text{HLLC}}.
\]

Under the CFL like condition (3.46), \( U_i^n \) is a convex sum of the states \( U_i^n, U_{R, i-\frac{1}{2}}^{n, \text{HLLC}} \) and \( U_{L, i+\frac{1}{2}}^{n, \text{HLLC}} \). The definitions (3.47)-(3.48) allow to apply lemma 3.4 and thus \( U_{R, i-\frac{1}{2}}^{n, \text{HLLC}} \) and \( U_{L, i+\frac{1}{2}}^{n, \text{HLLC}} \) are in \( A \). Since \( U_i^n \in A \), involving the convex property of \( A \), we obtain \( U_i^{n+1} \in A \).

The conservation of the total energy \( (E + \rho C_v T_i)^{n+1} \) is a direct consequence of (3.62) since we have

\[
(E + \rho C_v T_i)^{n+1} = (E + \rho C_v T_i)^n - \frac{\Delta t}{\Delta x} \left( \alpha_{i+\frac{1}{2}} \tilde{E}_{i+\frac{1}{2}}^{n, \text{HLLC}} - \alpha_{i-\frac{1}{2}} \tilde{E}_{i-\frac{1}{2}}^{n, \text{HLLC}} \right).
\]

The proof is completed. \( \square \)

We conclude the present section when establishing that the considered scheme (3.62) is asymptotic preserving. We show that the standard diffusion regime is recovered in the relaxation limit. Following the rescaling introduced into the system (2.8)-(2.8), we consider the Knudsen number \( \epsilon \) which appears in front of the time derivative terms and in the relaxation terms. Invoking such a rescaling, the scheme (3.62) rewrites as follows:

\[
\epsilon \frac{E_{i+1}^{n+1} - E_{i}^{n}}{\Delta t} + \frac{1}{\Delta x} \left( \alpha_{i+\frac{1}{2}} \tilde{E}_{i+\frac{1}{2}}^{n, \text{HLLC}} - \alpha_{i-\frac{1}{2}} \tilde{E}_{i-\frac{1}{2}}^{n, \text{HLLC}} \right) =
\]

\[
- \left( 1 - \alpha_{i+\frac{1}{2}} \frac{\Delta t}{\Delta x} \left( \alpha_{i+\frac{1}{2}} \left( T_{i+1/2}^{n, \text{HLLC}} \right)^4 - \left( E_{i}^{n} - \frac{E_{i}^{n}}{b_L^{i+\frac{1}{2}}} \right) \right) \right)
\]

\[
- \left( 1 - \alpha_{i-\frac{1}{2}} \frac{\Delta t}{\Delta x} \left( \alpha_{i-\frac{1}{2}} \left( T_{i-1/2}^{n, \text{HLLC}} \right)^4 - \left( E_{i}^{n} - \frac{E_{i}^{n}}{b_R^{i-\frac{1}{2}}} \right) \right) \right),
\]

\[
\epsilon \frac{U_{i+1}^{n+1} - U_{i}^{n}}{\Delta t} + \frac{c^2}{\Delta x} \left( \alpha_{i+\frac{1}{2}} \tilde{P}_{i+\frac{1}{2}}^{n, \text{HLLC}} - \alpha_{i-\frac{1}{2}} \tilde{P}_{i-\frac{1}{2}}^{n, \text{HLLC}} + (\alpha_{i-\frac{1}{2}} - \alpha_{i+\frac{1}{2}}) P_{i}^{n} \right) =
\]
\[-(1 - \alpha_{i+\frac{1}{2}} b_{L}^{i+\frac{1}{2}} + \alpha_{i-\frac{1}{2}} b_{R}^{i-\frac{1}{2}}) F_{i}^{n}, \quad (3.64b)\]

\[
\epsilon \left(\rho C_{v} T^{n+1} - \rho C_{v} T^{n} \right)_{i} \Delta t = \frac{1 - \alpha_{i+\frac{1}{2}} b_{L}^{i+\frac{1}{2}}}{\Delta x} \left( a \left( T_{i+\frac{1}{2}}^{*,HLLC} \right)^{4} - \left( E^{n} - \frac{F_{i}^{n}}{b_{L}^{i+\frac{1}{2}}} \right) \right)
- \frac{1 - \alpha_{i-\frac{1}{2}} b_{R}^{i-\frac{1}{2}}}{\Delta x} b_{R}^{i-\frac{1}{2}} \left( a \left( T_{i-\frac{1}{2}}^{*,HLLC} \right)^{4} - \left( E^{n} - \frac{F_{i}^{n}}{b_{R}^{i-\frac{1}{2}}} \right) \right). \quad (3.64c)\]

where the definition of \( \alpha_{i+\frac{1}{2}} \) becomes

\[
\alpha_{i+\frac{1}{2}} = \frac{\epsilon (b_{L}^{i+\frac{1}{2}} - b_{L}^{i+\frac{1}{2}})}{\epsilon (b_{R}^{i+\frac{1}{2}} - b_{L}^{i+\frac{1}{2}}) + c\sigma_{i+\frac{1}{2}} \Delta x}. \quad (3.65)\]

The behavior of the rescaled scheme in the limit of \( \epsilon \) to zero is given in the following result which is nothing but the discrete version of 5) in theorem 2.1:

**Theorem 3.6.** Assume the wavespeed \( b_{L,R}^{i+\frac{1}{2}} \) to be given by

\[
b_{L}^{i+\frac{1}{2}} = \min \left( 0, c f_{i}^{n}, c f_{i}^{n} - \chi_{i}^{n} \frac{1 - f_{i}^{n}}{1 + f_{i}^{n}} + \lambda^{n} (U_{i}^{n}) \right), \quad (3.66)\]

\[
b_{R}^{i-\frac{1}{2}} = \max \left( 0, c f_{i}^{n}, c f_{i}^{n} - \chi_{i}^{n} \frac{1 - f_{i}^{n}}{1 + f_{i}^{n}} + \lambda^{n} (U_{i}^{n}) \right), \quad (3.67)\]

so that the conditions (3.47)-(3.48) are satisfied. With \( \epsilon \) small, the diffusion limit of the scheme (3.64)-(3.65) is given by

\[
\begin{align*}
E_{i}^{n} &= a(T_{i}^{n})^{4}, \\
F_{i}^{n} &= 0, \\
\frac{(E + \rho C_{v} T^{n+1}) - (E + \rho C_{v} T^{n})}{\Delta t} &= \frac{c}{3 \Delta x^{2}} \left( \frac{1}{\sigma_{i+\frac{1}{2}}} (E_{i+1}^{n} - E_{i}^{n}) + \frac{1}{\sigma_{i-\frac{1}{2}}} (E_{i-1}^{n} - E_{i}^{n}) \right). \\
\end{align*} \quad (3.68)\]

**Proof.** From (3.65), we immediately deduce that

\[
\lim_{\epsilon \to 0} \alpha_{i+\frac{1}{2}} = 0.
\]

Now, when considering (3.64b), we obtain the following asymptotic behavior:

\[
F_{i}^{n} = 0.
\]

Similarly, the relation (3.64a) rewrites

\[
\left( b_{R}^{i-\frac{1}{2}} \left( a \left( T_{i-\frac{1}{2}}^{*,HLLC} \right)^{4} - E_{i}^{n} \right) - b_{L}^{i+\frac{1}{2}} \left( a \left( T_{i+\frac{1}{2}}^{*,HLLC} \right)^{4} - E_{i}^{n} \right) = 0. \quad (3.69)\right.
\]

In addition, the equation (5.55) governing the matter temperature \( T_{L,R}^{*,HLLC} \) reads in the asymptotic regime

\[
\rho C_{v} T_{L,R}^{*,HLLC} + a \left( T_{L,R}^{*,HLLC} \right)^{4} = \rho C_{v} T_{L,R} + E_{L,R},
\]
to obtain
\[ a \left( T^*_{R,i-\frac{1}{2}} \right)^4 - E^*_i = \rho C_v \left( T^*_i - T^*_{R,i-\frac{1}{2}} \right), \]
\[ a \left( T^*_{L,i+\frac{1}{2}} \right)^4 - E^*_i = \rho C_v \left( T^*_i - T^*_{L,i+\frac{1}{2}} \right). \]

(3.70)  

(3.71)

By solving (3.69)-(3.70)-(3.71), we have
\[ T^*_{R,i-\frac{1}{2}} = T^*_{L,i+\frac{1}{2}} = T^*_i \quad \text{and} \quad E^*_i = a(T^*_i)^4 \]

The proof will be concluded when establishing the diffusion equation (3.68). First, we emphasize the behavior of the wavespeeds \( b^i_{L,i} \) and \( b^i_{R,i} \). Indeed, involving the definition of \( b^i_{L,R} \), given by (3.66)-(3.67), and the wavespeed limitations (3.44)-(3.45), with \( F^i = 0 \) we obtain
\[ b^i_{L,i} = \frac{c}{\sqrt{3}} \quad \text{and} \quad b^i_{R,i} = \frac{c}{\sqrt{3}}. \]

(3.72)

Now, the standard HLL flux function \( F^{HLL} \), defined by (3.23), reads in the asymptotic regime
\[ F^{HLL}_{i+\frac{1}{2}} = -\frac{c}{2\sqrt{3}} (E^i_{i+1} - E^i_i). \]

As a consequence, (3.64a) and (3.64c) rewrite in the following form:
\[ \frac{\varepsilon}{\Delta t} (E + \rho C_v T)^{n+1}_{i} - (E + \rho C_v T)^{n}_{i} = \]
\[ \frac{c}{2\sqrt{3}\Delta x} \left( \alpha^i_{i+\frac{1}{2}} (E^i_{i+1} - E^i_i) + \alpha^i_{i-\frac{1}{2}} (E^i_{i-1} - E^i_i) \right). \]

(3.73)

Involving (3.72), the parameter \( \alpha^i_{i+\frac{1}{2}} \) reads as follows:
\[ \alpha^i_{i+\frac{1}{2}} = \frac{2\varepsilon}{2\varepsilon + \sqrt{3}\Delta x \sigma^i_{i+\frac{1}{2}}}. \]

Hence, from (3.73) we deduce
\[ \frac{(E + \rho C_v T)^{n+1}_{i} - (E + \rho C_v T)^{n}_{i}}{\Delta t} = \frac{c}{2\varepsilon \Delta x \sqrt{3} + 3\sigma^i_{i+\frac{1}{2}} \Delta x^2} (E^i_{i+1} - E^i_i) + \]
\[ \frac{c}{2\varepsilon \Delta x \sqrt{3} + 3\sigma^i_{i-\frac{1}{2}} \Delta x^2} (E^i_{i-1} - E^i_i). \]

The expected diffusion equation (3.68) is thus obtained as soon as \( \varepsilon \) tends to zero. The proof is achieved. \( \square \)

4. The 2D extension. The above HLLC scheme is now extended to the full space dimension \( M_1 \) model given by (2.1). A Cartesian grid is considered to approximate the solution. Let us note that extensions involving other grid generation methods (unstructured [12], Cartesian cut cell [15]) can be obtained. We propose to
adopt a dimensional operator splitting strategy. In a first step, we approximate the following 1D system:

$$
\begin{aligned}
\partial_t E + \partial_x F_x &= \beta c \sigma (a T^4 - E), \\
\frac{1}{c} \partial_t F_x + c \partial_x P_{xx} &= -\beta \sigma F_x, \\
\frac{1}{c} \partial_t F_y + c \partial_x P_{xy} &= -\beta \sigma F_y, \\
\partial_t (\rho C_v T) &= -\beta c \sigma (a T^4 - E),
\end{aligned}
$$

(4.1)

while, into the second step, the following system will be considered:

$$
\begin{aligned}
\partial_t E + \partial_y F_y &= (1 - \beta) c \sigma (a T^4 - E), \\
\frac{1}{c} \partial_t F_x + c \partial_y P_{xy} &= -(1 - \beta) \sigma F_x, \\
\frac{1}{c} \partial_t F_y + c \partial_y P_{yy} &= -(1 - \beta) \sigma F_y, \\
\partial_t (\rho C_v T) &= -(1 - \beta) c \sigma (a T^4 - E),
\end{aligned}
$$

(4.2)

where $\beta$ is a given parameter in $[0, 1]$. The main idea of the present splitting lies on the choice of the source terms. Indeed, the relaxation terms are split over each step involving a parameter $\beta$. To ensure consistency of the splitting, this parameter $\beta$ will belong to $[0, 1]$. A relevant choice will be proposed in the next section devoted to the numerical experiments.

In the present section, we will just describe the first step since the second one is analogous reversing the role played by each dimension component $(F_x, P_{xx}, P_{xy})$ and $(F_y, P_{xy}, P_{yy})$. Following the ideas introduced to approximate the 1D model, we propose to consider an approximate Riemann solver and thus define an HLLC type scheme. One of the main difference with the 1D model lies on the source terms which is now multiply by $\beta$ (respectively $1 - \beta$). We impose to preserve the same discrete form of the source terms. Such a choice is crucial to enforce the relevant asymptotic behavior of the scheme; namely the asymptotic preserving property.

After (3.58)-(3.59), the flux function involved in the Riemann solver has to satisfy:

$$
\begin{aligned}
\mathcal{F}^{HLLC}_{L,R} &= \alpha \mathcal{F}^{HLL} + (1 - \alpha) \mathcal{S}^a_{L,R}, \\
\mathcal{S}_{L,R} &= \beta b_{L,R} \left( U_{L,R}^a - U_{L,R} \right),
\end{aligned}
$$

where $\alpha$ is once again defined by (3.17) and

$$
\mathcal{U} = \left( E, \frac{F_x}{c}, \frac{F_y}{c} \right) \quad \text{and} \quad \mathcal{F} = \left( F_x, c P_{xx}, c P_{xy} \right).
$$

(4.3)

Following (3.54), the states $U_{L,R}^a$ are given by

$$
U_{L,R}^a = \begin{pmatrix}
\frac{a(T_{L,R}^*)^4}{c} \\
0 \\
0
\end{pmatrix},
$$

(4.4)

where $T_{L,R}^*$ is solution of the following equation (see (3.55)):

$$
\rho C_v T_{L,R}^* + (1 - \alpha) a(T_{L,R}^*)^4 = \rho C_v T_{L,R} + (1 - \alpha) \left( E_{L,R} - \left( \frac{F_x}_{L,R} b_{L,R} \right) \right).
$$

(4.5)
As usual (see [14, 22] or the equations (3.23)-(3.24)) we have set

$$
\tilde{f}^{HLL} = \frac{1}{b_R - b_L} (b_R \mathcal{F}_L - b_L \mathcal{F}_R - b_L b_R (\mathcal{U}_L - \mathcal{U}_R)).
$$

Now, we characterize the star region states $\mathcal{U}^*_{L,R}$. To access such an issue, we involve the Rankine-Hugoniot relations which reads:

$$
b_{L,R} \left( \mathcal{U}^*_{L,R} - \mathcal{U}_{L,R} \right) = \tilde{f}^{HLL} - \mathcal{F}_{L,R},
$$

to immediately deduce

$$
\mathcal{U}^*_{L,R} = \alpha \mathcal{U}^* - (1 - \alpha) \mathcal{U}_{L,R},
$$

(4.6)

where

$$
\mathcal{U}^*_{L,R} = \beta \mathcal{U}^0_{L,R} + (1 - \beta) \mathcal{U}^0_{L,R},
$$

$$
\mathcal{U}^0_{L,R} = \mathcal{U}_{L,R} - \frac{1}{b_{L,R}} \mathcal{F}_{L,R}.
$$

The state $\mathcal{U}^*_{L,R}$ is defined as the usual HLL star region state (see [14, 22] and equation (3.21)-(3.22)):

$$
\mathcal{U}^*_{L,R} = \frac{1}{b_R - b_L} (b_R \mathcal{U}_R - b_L \mathcal{U}_L - (\mathcal{F}_R - \mathcal{F}_L)).
$$

Now, the approximate Riemann solver is achieved as soon as the matter temperature $T^*_{L,R}$ is defined. Once again, we enforce the same discretization of the source terms. Involving (3.61), we impose

$$
S^T_{L,R} = -\beta b_{L,R} (1 - \alpha) \left( a (T^*_{L,R})^4 - E^0_{L,R} \right),
$$

which coincides with (3.61) detailed in the 1D model when multiplied by $\beta$. Since we have

$$
S^T_{L,R} = b_{L,R} \rho C_v \left( T^*_{L,R} - T^*_{L,R} \right),
$$

we immediately deduce

$$
\rho C_v T^*_{L,R}^{HLL} = \rho C_v T^*_{L,R} - \beta (1 - \alpha) \left( a (T^*_{L,R})^4 - E^0_{L,R} \right),
$$

(4.7)

$$
= \beta \rho C_v T^*_{L,R} + (1 - \beta) \rho C_v T^*_{L,R}.
$$

Let us note that

$$
S^T_{L,R} = (1 - \alpha) S^E_{L,R},
$$

(4.8)

where $S^E_{L,R}$ is the first component of $S^T_{L,R}$. This remark will be useful when establishing the conservation of the approximate total energy.

Now, we turn establishing that the star states, involved in the approximate Riemann solver, remain in $\mathcal{A}$ while the matter temperature is positive.

**Lemma 4.1.** Assume $b_L < 0$ and $b_R > 0$. Let us assume that $\mathcal{U}^0_{L,R}$ are in $\mathcal{A}$. Then, the vectors $\mathcal{U}^*_{L,R}$, defined by (4.6), belong in $\mathcal{A}$. In addition, the matter temperature is positive: $T^*_{L,R} > 0$. 

Let us emphasize that the assumption $\mathcal{U}_{L,R}^0 \in A$ turns out to be conditions to be satisfied by the velocities $b_L$ and $b_R$. These conditions are nothing but the 2D extension of (3.44)-(3.45). They are specified in the following result:

**Lemma 4.2.** Let $\mathcal{U}$ be in $A$ and, with $b \neq 0$, $\mathcal{U}^0$ be defined as follows:

$$\mathcal{U}^0 = \mathcal{U} - \frac{1}{b} \mathcal{F}.$$ 

Define $b^\pm$ by

$$b^\pm(\mathcal{U}) = \frac{f_x - f_x \chi_x - f_y \chi_y \pm \sqrt{\delta}}{1 - f_x^2 - f_y^2},$$

$$\delta = (f_x - f_x \chi_x - f_y \chi_y)^2 - (1 - f_x^2 - f_y^2)(f_x^2 - \chi_x^2 - \chi_y^2) > 0,$$

where we have set

$$\begin{cases} f_x = F_x/(cE), & f_y = F_y/(cE), \\ \chi_x = P_{xx}/E, & \chi_y = P_{xy}/E. \end{cases}$$

Assume that

$$b \geq \max(b^+(\mathcal{U}), b^-(\mathcal{U})) \quad \text{or} \quad b \leq \min(b^+(\mathcal{U}), b^-(\mathcal{U}))$$

and

$$b^2 \geq c f_x b, \quad (4.12)$$

then $\mathcal{U}^0$ belongs to $A$.

Before we establish this lemma, let us emphasize the consequence implies by such a result. Indeed, the vectors $\mathcal{U}_{L,R}$ and $\mathcal{U}_{L,R}^0$ satisfy the assumptions stated lemma 4.2. Then we have $\mathcal{U}_{L,R}^0$ in $A$ as soon as $b_{L,R}$ satisfies (4.11)-(4.12). Next, the assumptions of lemma 4.1 are satisfied. First, we establish lemma 4.2.

**Proof.** By definition, we have

$$\mathcal{U}^0 = \begin{pmatrix} E - \frac{F_x}{b} \\ \frac{F_x - c^2 P_{xx}/b}{b} \\ \frac{F_y - c^2 P_{xy}/b}{b} \end{pmatrix},$$

which must satisfy both positiveness and flux limitation properties. The positiveness is established as soon as we have

$$E - \frac{F_x}{b} = E \left(1 - \frac{c}{b} f_x \right) > 0.$$ 

This inequality is satisfied when involving (4.12). Now, we turn considering the flux limitation which reads as follows:

$$\left(\frac{F_x - c^2 P_{xx}}{b} \right)^2 + \left(\frac{F_y - c^2 P_{xy}}{b} \right)^2 \leq c^2 \left(\frac{E - F_x}{b} \right)^2.$$ 

Involving the notations (4.10), we rewrite

$$\left(\frac{b}{c} f_x - \chi_x \right)^2 + \left(\frac{b}{c} f_y - \chi_y \right)^2 \leq \left(\frac{b}{c} - f_x \right)^2.$$
After usual computations, we obtain

\[(1 - f_x^2 - f_y^2) \left( b - b^- \right) \left( b - b^+ \right) > 0, \]

and the proof is completed. □

Now, we turn proving lemma 4.1.

**Proof.** First, let us note that the assumption $U^0_{L,R} \in A$ implies $U^{*,HLL} \in A$. Indeed, we have

\[U^{*,HLL} = \frac{b_R}{b_R - b_L} U^0_R + \frac{-b_L}{b_R - b_L} U^0_L.\]

Since $A$ is a convex set, we immediately deduce that $U^{*,HLL} \in A$.

Now, involving (4.6) and the convex property of $A$, we have just to prove that $U^a_{L,R} \in A$ to ensure that $U^{*,HLL}_{L,R}$ belongs to $A$. Let us recall that $U^a_{L,R} = \beta U^0_{L,R} + (1 - \beta) U^0_{L,R}$. As a consequence, the result is established as soon as we have $U^0_{L,R} \in A$. When $U^0_{L,R}$ being defined by (4.4), the result arises as soon as $T^*_R$ is shown to be positive. Since $T^*_R$ is solution of (4.5), we can apply lemma 3.3 and thus to obtain $T^*_R > 0$. The proof is thus completed. □

We have describe an approximate Riemann solver corresponding to the system (4.1). The same analysis yields to an approximate Riemann solver but for the system (4.2). Both approximate Riemann solvers are now used to integrate a 2D numerical scheme on a Cartesian grid. To simplify, the mesh size $\Delta x$ and $\Delta y$ will be uniform. The time increment is evaluated according with the following CFL like conditions:

\[
\begin{align}
\Delta t & \leq \max_{i \in Z} \left( \frac{b_{L,i}^{x,i+\frac{1}{2}}}{\Delta x} \right), \\
\Delta t & \leq \max_{i \in Z} \left( \frac{b_{R,i}^{x,i-\frac{1}{2}}}{\Delta x} \right), \\
\Delta t & \leq \max_{i \in Z} \left( \frac{b_{L,i}^{y,j+\frac{1}{2}}}{\Delta y} \right), \\
\Delta t & \leq \max_{i \in Z} \left( \frac{b_{R,i}^{y,j-\frac{1}{2}}}{\Delta y} \right),
\end{align}
\]

where the wavespeeds are evaluated involving the exact 2D eigenvalues given by (2.4). These velocities have to be restricted according to lemma 4.1. The following formulas are proposed:

\[
\begin{align}
\frac{b_{L,i}^{x,i+\frac{1}{2}}} = \min \left( 0, c f_{x,i}, b^+ (U_{i,j}^n), b^- (U_{i,j}^n), \lambda^- (U_{i,j}^n) \right), \\
\frac{b_{R,i}^{x,i-\frac{1}{2}}} = \max \left( 0, c f_{x,i}, b^+ (U_{i,j}^n), b^- (U_{i,j}^n), \lambda^+ (U_{i,j}^n) \right),
\end{align}
\]

where $b^\pm$ are defined by (4.9). Concerning $b_{L,R,i,j}^{y,j+\frac{1}{2}}$, similar formulas have to be considered when reversing the role of $f_x$ and $f_y$.

After computations, the scheme reads as follows:

\[
\begin{align}
E^{n+1}_{i,j} = E_{i,j}^n - \Delta t \frac{\Delta x}{\Delta x} \left( \frac{P_{HLLC,xx}}{E_{i,j}^{x,i}} - \frac{P_{HLLC,xx}}{E_{i,j}^{x,i-\frac{1}{2}}} \right) - \\
\Delta t \frac{\Delta y}{\Delta y} \left( \frac{P_{HLLC,yy}}{E_{i,j}^{y,j}} - \frac{P_{HLLC,yy}}{E_{i,j}^{y,j-\frac{1}{2}}} \right), \\
\frac{(F_x)^{n+1}_{i,j}}{c} = \frac{(F_x)^{n}_{i,j}}{c} - \Delta t \frac{\Delta x}{\Delta x} \left( \frac{P_{HLLC,xx}}{E_{i,j}^{x,i}} - \frac{P_{HLLC,xx}}{E_{i,j}^{x,i-\frac{1}{2}}} \right) - \\
\Delta t \frac{\Delta y}{\Delta y} \left( \frac{P_{HLLC,yy}}{E_{i,j}^{y,j}} - \frac{P_{HLLC,yy}}{E_{i,j}^{y,j-\frac{1}{2}}} \right), \\
\frac{(F_y)^{n+1}_{i,j}}{c} = \frac{(F_y)^{n}_{i,j}}{c} - \Delta t \frac{\Delta x}{\Delta x} \left( \frac{P_{HLLC,xx}}{E_{i,j}^{x,i}} - \frac{P_{HLLC,xx}}{E_{i,j}^{x,i-\frac{1}{2}}} \right) - \\
\Delta t \frac{\Delta y}{\Delta y} \left( \frac{P_{HLLC,yy}}{E_{i,j}^{y,j}} - \frac{P_{HLLC,yy}}{E_{i,j}^{y,j-\frac{1}{2}}} \right),
\end{align}
\]
\[
\begin{align*}
\frac{\Delta t}{\Delta y} & \left( \left( \tilde{p}_{y, L}^{\text{HLLC}} \right)_{i,j} \right)_{i,j} + \frac{\Delta t}{\Delta x} \left( \left( \tilde{p}_{y, R}^{\text{HLLC}} \right)_{i,j} \right)_{i,j} , \quad (4.16c) \\
\rho C_v T_{i,j}^{n+1} & = \rho C_v T_{i,j}^n + \frac{\Delta t}{\Delta x} \left( \left( S_{x, L}^T \right)_{i+1/2,j} - \left( S_{x, R}^T \right)_{i-1/2,j} \right) + \\
& + \frac{\Delta t}{\Delta y} \left( \left( S_{y, L}^T \right)_{i,j+1/2} - \left( S_{y, R}^T \right)_{i,j-1/2} \right) . \quad (4.16d)
\end{align*}
\]

Let us conclude when giving the main properties satisfied by the approximate solution.

**Theorem 4.3.** Let \( U_{i,j}^n \) be in \( A \) and \( T_{i,j}^n \) be positive. Assume the CFL restriction (4.13) where the wavespeeds in each direction are restricted according to lemma 4.1. Then, we have \( U_{i,j}^{n+1} \) in \( A \), \( T_{i,j}^{n+1} \) positive and the total energy is conserved.

We omit the proof of the above result. Indeed, the proof is analogous to the proof of theorem 3.5. Just, let us emphasize that \( U_{i,j}^{n+1} \in A \) is a direct consequence of lemma 4.1. Concerning the conservation of the total energy, the result is implied by the relation (4.8).

The last point we develop concerns the asymptotic preserving property of the scheme. We do not detail the computations and the reader is referred to the section devoted to the 1D model. However, after introducing the rescaling based on the Knudsen number \( \epsilon \), the 2D version of theorem 3.6 holds true:

**Theorem 4.4.** Assume that the wavespeeds are given by (4.14)-(4.15). With \( \epsilon \) small, the diffusion limit behavior of the scheme (4.16) is as follows:

\[
\begin{align*}
E_{i,j}^n &= a(T_{i,j}^n)^4 , \\
F_{i,j}^n &= 0 , \\
\frac{\Delta t}{\Delta x^2} & \left( \frac{1}{\sigma_{i+1/2,j}} \left( E_{i+1,j}^n - E_{i,j}^n \right) + \frac{1}{\sigma_{i-1/2,j}} \left( E_{i-1,j}^n - E_{i,j}^n \right) \right) + \\
& + \frac{1}{\sigma_{i,j+1/2}} \left( E_{i,j+1}^n - E_{i,j}^n \right) + \frac{1}{\sigma_{i,j-1/2}} \left( E_{i,j-1}^n - E_{i,j}^n \right) .
\end{align*}
\]

5. Numerical experiments. Now we turn considering numerical applications to illustrate the interest of the present method in both one and two space dimensions.

Two main numerical aspects will be considered in this section. The first will be devoted to the influence of the numerical wavespeeds \( b_L \) and \( b_R \) which enclose the Riemann problem in HLLC schemes. These wavespeeds will be taken either as in (3.66)-(3.67) or as \( b_R = -b_L = c \) to enforce the maximal stability. The first choice will be denoted HLLC-var scheme and the second HLLC-c scheme.

The second aspect concerns the influence of the asymptotic preserving modification of the HLLC scheme introduced in 3. The scheme with or without this modification will be denoted AP-HLLC or HLLC scheme, leading to four variants (HLLC-c, HLLC-var, AP-HLLC-c, AP-HLLC-var) that will be compared. All the numerical experiments are performed using an Intel Pentium Centrino with 1.7 GHz clock frequency. The 2D computations given in section 5.4 need about one minute CPU time to be completed.

5.1. Marshak wave. The first problem comes from [24]. This test problem consists of a slab of material with opacity \( \sigma = 100 \), and \( \rho C_v = 10^{-4} \), extending from \( x = 0 \) to \( x = 0.1 \). A temperature source with \( T = 1000 \), on the left side generates
Fig. 5.1. Radiation temperature for $t_1 = 1.33 \times 10^{-9}$, $t_2 = 1.33 \times 10^{-8}$ and $t_3 = 1.33 \times 10^{-7}$. Results from the HLLC-var and AP-HLLC-var schemes are compared with the kinetic reference solution obtained in [24].

Fig. 5.2. Radiation temperature for $t = 1.33 \times 10^{-7}$ obtained thanks to the HLLC-c and HLLC-var, AP-HLLC-c and AP-HLLC-var are compared with the X kinetic reference solution obtained in [24].

A thermal wave into the initially cold medium, which is at equilibrium with an initial temperature $T = 300$. In this test case we use a mesh with ten cells.

Comparison of $M_1$ solution computed using the AP-HLLC-var scheme with $M_1$ solution computed using the HLLC-var scheme and a reference solution obtained by full transport calculation (see [24]) is shown in figure 5.1 at three times ($t_1 = 1.33 \times 10^{-9}$, $t_2 = 1.33 \times 10^{-8}$, $t_3 = 1.33 \times 10^{-7}$).
Fig. 5.3. Steady radiation temperature obtained thanks to the HLLC-var and AP-HLLC-var schemes on two different meshes are compared with the exact solution. A material opacity $\sigma = 100$ is used.

Fig. 5.4. Steady radiation temperature obtained thanks to the HLLC-var and AP-HLLC-var schemes on two different meshes are compared with the exact solution. The material opacities $\sigma = 100$ for $x < 5$ and $\sigma = 200$ for $x > 5$ are used.

In this computation the cell size $\Delta x = 0.01$ does not sample the mean free path $\lambda = 1/\sigma = 0.01$. As we expected the $M_1$ solution computed using the HLLC-c scheme clearly overestimates the radiative energy, mostly in early times whereas the $M_1$ solution computed using the AP-HLLC-var scheme gives a much better agreement with the reference solution.
The influence of the choice of the numerical wavespeeds $b_L$ and $b_R$ is illustrated in figure 5.2. We compare, on the same test case, at time $t_3$, the four variants of our scheme (HLLC-c, HLE-var, AP-HLLC-c, AP-HLLC-var) with the reference solution. Obviously, taking too large numerical wavespeeds ($b_L = -c$ and $b_R = +c$) brings a too large amount of numerical diffusion. Improving the HLLC-c scheme by using sharper wavespeed estimates or by using the asymptotic preserving modification gives roughly the same improvement of accuracy and, as expected, the best result is obtained with the AP-HLLC-var variant combining the two modifications.

5.2. Opaque materials. We now examine two problems which involve opaque materials and where we are able to compute the exact steady state solution of the equilibrium diffusion model.

The first problem comes from [11]. This test problem consists of a slab of material with opacity $\sigma = 100$, and $\rho C_v = 1$, extending from $x = 0$ to $x = 10$. A temperature source with $T = 1$, on the left side generates a thermal wave into the initially cold slab, which is at equilibrium and has an initial temperature of $T = 10^{-3}$. A vacuum boundary condition is imposed at $x = 10$. The units are chosen such that $c = a = 1$. Two simulations are performed with two different meshes of respectively 20 and 100 cells, so that the mean free path is not resolved.

Figure 5.3 shows the radiation temperature at steady state for a simulation run with the AP-HLLC-var scheme on the two different meshes. The two computations produced almost identical results, both very close to the exact steady solution of the equilibrium diffusion model.

For the second problem we keep the same parameters except the opacity. We introduce a low-opacity region with $\sigma = 100$ which extend from $x = 0$ to $x = 5$ and a high-opacity region with $\sigma = 200$ which extend from $x = 5$ to $x = 10$.

Figure 5.4 shows the radiation temperature for a simulation run with the AP-
HLLC-var scheme on the two meshes. A good agreement with the exact solution of
the equilibrium diffusion model can be found again.

Figure 5.5 illustrates the influence of the asymptotic preserving modification. We
use here the finest mesh with 100 cells. The HLLC-var scheme and the AP-HLLC-var
are compared. Again, the solution of HLLC-var scheme is far away from the exact
solution. On the other hand, in both cases the boundary conditions are satisfied. The
upwind HLLC-var scheme is too dissipative and is not able to see the transition area
between the low and high opacity regions.

\begin{center}
\includegraphics[width=0.5\textwidth]{fig5.6.png}
\end{center}

\textbf{Fig. 5.6.} Steady radiation temperature obtained thanks to the HLLC-var and AP-HLLC-var
are compared with the exact solution. The material opacities $\sigma = 0.1$ for $x < 5$ and $\sigma = 100$ for
$x > 5$ are used.

\textbf{5.3. Hybrid case: transparent to opaque transition.} For this case, an
hybrid problem for checking the transition between transparent and opaque regions is
considered. This test problem consists of a slab with a region of transparent material
with opacity $\sigma = 0.1$, extending from $x = 0$ to $x = 5$ and a region of opaque material
with $\sigma = 100$, extending from $x = 5$ to $x = 10$. A temperature source with $T = 1$,
on the left side generates a thermal wave into the initially cold medium, which is
at equilibrium and has an initial temperature of $T = 10^{-3}$. A vacuum boundary
condition is imposed at $x = 10$. The units are chosen such that $c = a = 1$.

Figure 5.6 shows the steady radiation temperature obtained from the AP-HLLC-
var scheme which was run with 100 cells compared with the exact steady solution of
the equilibrium diffusion model. A good agreement can be observed. The AP-HLLC-
var scheme proves to be able to handle the wave crossing the interface between the
transparent and opaque regions.

This conclusion is enforced by the figure 5.7 where the material and radiative
temperatures are plotted at five different times. The last time is taken sufficiently
high to be close to the steady state. The phenomena in the opaque material is a
Marshak wave except of a small preheating area where the material temperature is
not the same as the radiative temperature. In this area, the transport is dominant,
and the diffusion assumption is not verified.
5.4. Two dimensional case. The fourth problem is a two dimensional problem developed to focus on purely two dimensional effects. A Cartesian mesh made of 80 × 40 cells is used. In this problem, we consider free streaming beam adjacent to some section of dense, opaque material. The opaque region extends from x = 0 to x = 0.5 and from y = 0 to y = 0.5. Outside, we consider a transparent region which extends from x = 0 to x = 2 and from y = 0 to y = 2. In the dense material \( \rho C_v = 8.6 \times 10^4 \), \( \sigma = 2 \times 10^5 \). The outside material is purely transparent, i.e. \( \sigma = 0 \). The geometry is summarized on figure 5.8.

A radiative temperature \( T = 5802000 \) (\( = 5keV \)) is applied on the left side of the transparent material from \( y = 0.5 \) to \( y = 1 \) (see figure 5.8). Vacuum boundary condition are applied at all other boundaries. The initial temperature is \( T = 50000 \) in the dense material and \( T = 300 \) elsewhere. All the computations are run on a cartesian mesh of 80 × 40 cells and the parameter \( \beta \), introduced in (4.1), is defined as
Fig. 5.9. Radiation temperature at $t = 5 \times 10^{-8}$ obtained thanks to the HLLC-c and HLLC-var, AP-HLLC-c and AP-HLLC-var schemes.

Fig. 5.10. Material temperature at $t = 5 \times 10^{-8}$ obtained thanks to the HLLC-c and HLLC-var, AP-HLLC-c and AP-HLLC-var schemes.

follows:

$$\beta = \begin{cases} 
\left( \frac{f \cdot n}{T} \right)^2 & \text{if } f \neq 0, \\
\frac{1}{2} & \text{if } f = 0,
\end{cases}$$

where $n$ is the outward normal of the cell interface. The simulation is stopped at the
time \( t = 5 \times 10^{-8} \).

The expected solution is very simple. In the upper part, from \( y = 0.5 \) to \( y = 1 \) the solution is a translation of the left boundary condition, the radiative temperature is \( T = 5802000 \) and the photons remains in free streaming (\( f \approx 1 \)). In the lower part, from \( y = 0 \) to \( y = 0.5 \) the solution is constant in time because there is no photons which are entering in this area. The line \( y = 0.5 \) is a stationary contact discontinuity for the \( M_1 \) system.

In the figures (5.9-5.11), we examine the ability of the various variants of our scheme to capture this solution. The figure 5.9 shows the radiative temperature, the figure 5.10 shows the material temperature in the obstacle, and the figure 5.11 shows the anisotropy factor \( f \), for each variant of the scheme.

Figure 5.9 illustrates the influence of the numerical wavespeeds \( b_L \) and \( b_R \). We compare the -c and the -var versions of both HLLC and AP-HLLC schemes. The numerical dissipation of the -c variant, especially in the y-direction, does not allow this schemes to preserve the contact discontinuity and we observe a lot of photons penetrating the lower part of the domain. On the other hand the contact discontinuity is nearly exactly preserved in the -var versions of the two schemes. More precisely, at a point \( y = 0.5 \), \( x > 0.5 \) on a cell interface in y-direction, in the "left" cell \( f_x = f_y \approx 0 \) and in the "right" cell \( f_x \approx 1, f_y \approx 0 \), and for the -var scheme \( b_L = -c/\sqrt{3}, b_R \approx 0 \) (3.66)-(3.67); the -c version (and every scheme using symmetric wavespeeds, \( b_L = -b_R \)) introduces there a numerical diffusion responsible for (nonphysical) penetration of photons in the lower part of the domain. The necessity of using sharp numerical wavespeeds estimates is clearly proved.

Figure 5.10 illustrates the improvement brought by the asymptotic preserving modification. Indeed for both HLLC-c and HLLC-var schemes the heating of the opaque medium is much more important without the asymptotic preserving modification. When using the HLLC-c scheme a large amount of photons penetrates the the
lower opaque region (wrong wavespeeds), which is too much heated (wrong behavior in the diffusion regime), and the material temperature raises and the medium emits energetic photons which perturb the solution in transparent regions.

Finally, it appears that we need to use sharp numerical wavespeeds estimates and asymptotic preserving modification, i.e. the AP-HLLC-var scheme, to capture with accuracy the solution of this problem.

6. Conclusion. In the present work, we have exhibited a new numerical method to approximate the solutions of the $M_1$ model of radiative transfer. This procedure is based on predictor-corrector scheme and it uses an HLLC scheme. A particular attention has been paid to satisfy the positiveness of the energy and the flux limitation property. As a consequence, the scheme has been proved to be robust. In addition, we have established the asymptotic preserving property of the scheme. The accuracy of the method has been ensured when considering approximate Riemann solver with a characteristic cone which is not necessary symmetric. Such an independent choice of the extreme approximate wavespeeds gives accurate numerical results into the simulations. Indeed, when simulations involving a shadow cone are performed, a scheme using an approximate Riemann solver with a symmetric characteristic cone involves very large numerical diffusion while our proposed scheme produces results in very good agreement with the physics.
